

Cohort — 124 paired recordings, 20 participants

A Residual across time scales

IQR over participants

B Residual ratio by recording

2 blocks, as written; bar = median and IQR over participants

C Beat-variable 8-13 Hz by recording

not identified as alpha; bar = median and IQR over participants

Descriptive evaluation of saved outputs, not independent validation. All EEG channels; recording median removed. Shaded bands are participant IQR. No signal-preservation or overall winner claim is supported. A uses chronological equal-beat blocks, not validation folds; more blocks raise the finite-sample noise floor. The 2-block ratio is the most optimistic local residual. Solid = as written; dashed = ECG-regressed (cannot see cardiac-shaped residual left in the file). B and C: one point per recording, summarised over participants. C is 8-13 Hz power in beat-variable removal relative to input; variable BCG and heartbeat-evoked neural activity are both possible. Blocks below 8 beats are left missing, not replaced. BCGNet outputs include time used to train the subject model (70/15/15 split, then applied to the full recording). AAS and PCA-OBS are not trained that way. Residual panels are not a matched in-sample comparison. Recordings without a usable output are excluded rather than substituted (AAS 16; PCA-OBS 16; BCGNet 11).
