Variable 8-13 Hz removal / input (%)

Local heartbeat RMS before and after correction. The uncorrected column and the corrected arms carry separate scales, each with its own colourbar: on one shared scale the corrected maps collapse into the bottom of the ramp and cannot be compared with each other. Absolute magnitudes are therefore comparable within a colourbar, not across them. All maps use saved EEG and participant-balanced summaries. More blocks raise the noise floor. Spatial similarity does not establish whether removed activity was neural.
